Interviewer Effects Theories of the Survey Response

Interviewer Effects

• Long recognized as an issue in the social sciences.

- One of a host of measurement issues in surveys.
- The result of the interview process involving *two* people engaged in a social interaction:
 - The respondent, whose attitudes we are interested in.
 - The interviewer, whose role is to administer the survey as uniformly as possible.

- Most research has been based on responses of whites and blacks to interviewers of same and dissimilar race; e.g. Schuman and Converse, Cotter et al., Davis.
- Respondents' opinions typically only affected on questions that are strongly connected with race.
- Other researchers have identified similar effects based on gender and other ethnic identification.
- Attempts to replicate in computer-based interviews (Krysan and Couper) have seen limited success.

Interviewer Effects Theories of the Survey Response

Theories of the Survey Response

- Traditional belief: Respondents have pre-formed opinions; may be unwilling to reveal true opinions to potentially critical interviewers.
 - Are respondents "donning the black mask" with different-race interviewers? (Davis)
 - Are respondents conforming to in-group expectations with same-race interviewers? (e.g. Noelle-Neumann)
- Zaller-Feldman theory: Respondents are sampling from considerations; presence of interviewer influences the sampling process.
 - The survey interview as an *intrusive* measure.
 - Attitudes, beliefs, and values that are recalled may be affected by the interviewer.

• Telephone survey conducted in February 2009.

- 659 complete or partial interviews with African American southerners.
- Stratified, representative sample using random-digit dialing with screen for black respondents.
- Of the 621 complete interviews, 303 were conducted by white interviewers; 318 interviews by other racial/ethnic groups (mostly black).

No substantial differences appear in responses to a similar question about progress for *other groups in society*, suggesting that the observed effects in the questions about African Americans are due to the immediacy of race in those interactions.

We believe, based on existing research, that some black respondents may have internalized white hostility towards continued allegations of discrimination and therefore are more reluctant to suggest to whites that racial progress in the South and America remains an elusive goal.

.

- Generally race-of-interviewer effects were consistent with expectations based on prior research, even when controlling for likely confounding factors.
- The magnitude of these effects seems to vary across issue domains.
- Distinct effects only appear to emerge in questions that *directly* touch on race; attitudes toward Barack Obama, for example, do not seem to be affected (results not presented here).

• Future Directions:

- Further research on respondents from other racial groups.
- Should consider a more complex research design to test whether the classical or Zaller-Feldman model explains interviewer effects.
- Attempt to produce a research design that is capable of identifying which are the *true* attitudes.

.

- Generally race-of-interviewer effects were consistent with expectations based on prior research, even when controlling for likely confounding factors.
- The magnitude of these effects seems to vary across issue domains.
- Distinct effects only appear to emerge in questions that *directly* touch on race; attitudes toward Barack Obama, for example, do not seem to be affected (results not presented here).
- Future Directions:
 - Further research on respondents from other racial groups.
 - Should consider a more complex research design to test whether the classical or Zaller-Feldman model explains interviewer effects.
 - Attempt to produce a research design that is capable of identifying which are the *true* attitudes.
